TITLE: Method of amplifying DNA fragment, apparatus for amplifying DNA fragment, method of assaying microorganisms, method of analyzing microorganisms and method of assaying contaminant

## BSPR:

In this case, a band having a luminous intensity less than the threshold is that of a DNA fragment having low amplification efficiency and low reproducibility. The band having the luminous intensity exceeding the threshold is that of a DNA fragment having high amplification efficiency and high reproducibility. Thus, only the DNA fragment having high amplification efficiency and high reproducibility can be analyzed by employing the band having the luminous intensity exceeding the threshold. Thus, reliability of information obtained by analysis is improved.

TITLE: Method of sampling, amplifying and quantifying segment of nucleic acid, polymerase chain reaction assembly having nanoliter-sized sample chambers, and method of filling assembly

## DEPR:

The data also shows that single DNA molecules or segments can be detected with the "TagMan" system when PCRs are confined to volumes of 100 nanoliters or less, preferably 60 nanoliters or less, by using capillaries with small diameters and relying on the fortuitously slow rate of diffusion. Many PCR reactions with single molecule sensitivity can be performed simultaneously in small spaces by confining PCR's to small regions in 3 dimensions as described in other embodiments of the present invention. The devices of the invention can be used to measure the number of template molecules in a sample simply by counting the number of positive reactions in replicate PCRs containing terminal dilutions of sample. Due to the closed system environment which prevents carryover contamination, and the ability to automate fluorescence detection, devices according to the present invention and methods for using the devices have significant potential for clinical uses of PCR. An assay based on presence versus absence of PCF product in replicate reactions may be more robust with respect to small changes in amplification efficiency than quantitative competitive assays or time-to-reach-threshold level assays that require assumptions about relative or absolute amplification rates.

Entered Medline: 20000509 AΒ The laboratory diagnosis of hepatitis B virus (HBV) infection is based mainly on serological assays. Yet the detection and quantitation of viral DNA is necessary when addressing directly the question of infectivity or when monitoring the viral load during therapy. Standard hybridization assays allow for exact quantitation, but their sensitivity is limited to 10(5)-10(6) viral genomes per ml of serum. The most sensitive tests for HBV DNA are nested PCR systems, which recognize virtually one molecule of the target DNA per reaction.

However, these assays only provide very coarse quantitative statements.

To

take advantage of both methods, a new assay for HBV DNA is described based on the commercial TagMan system. This assay is capable of quantifying HBV DNA from the theoretical lower limit up to 10(10) genome equivalents per ml of serum and, thus, covers the complete range of naturally occurring states of infections. The method was calibrated on the basis of serial plasmid dilutions and compared with a well-established nested PCR system. More than 100 HBV positive

sera

and serial dilutions of the Eurohep standard for both ad and ay subtypes were analyzed. The assay reliably detected all HBV positive samples. It shows minimal run-to-run deviations, allows for quantitation that covers eight orders of magnitude, and finally, completely avoids the risk of cross-contamination by PCR products. Thus, this technique

       . . . amplifies well. The slower rate of probe displacement with an
DETD
      exo.sup.- polymerase apparently requires more time at 60.degree. C. for
      efficient amplification than the exo.sup.+ polymerase.
      The time required by exo.sup.- polymerases can be reduced by slowly
      increasing the temperature from 60.degree.. .
      . . . 70.degree. C. to 94.degree. C. The melting curves were
DETD
      converted to melting peaks and displayed (FIG. 44). Note that the
      amplification efficiency of the CFTR fragment appears
      greater than the new fragment. The amplification
      efficiency can be rigorously determined by integrating the
      melting peak data as in Example 16.
      . . . patients infected with HIV or hepatitis C is important in
DETD
      prognosis and therapy. Using a control template and monitoring the
      efficiency of amplification of both control and
      natural templates during amplification, accurate quantification of
      initial template copy number is achieved.
DETD
      2. Maximizing the amplification efficiency by
      ensuring adequate time for primer annealing each cycle while:
DETD
      3. Maximizing the amplification efficiency by
      ensuring adequate time for product extension each cycle while:
      4. Initiating thermal cycling changes dependent on the level of
DETD
      fluorescence obtained or the current efficiency of
      amplification. For example, over-amplification and nonspecific
      reaction products can be minimized by terminating thermal cycling when
      the efficiency drops to a.
       . . denaturation, annealing, and extension), a change in
DETD
      fluorescence over temperature (product or probe Tm), or a change in
      extent of amplification (amplification yield and
      efficiency). These rates, Tm's and their first and second
      derivatives are used to determine optimal reaction parameters that
      include denaturation temperature.
      . . . dyes are used for the control of denaturation, control of
DETD
      extension, and to initiate thermal cycling changes at a certain
      amplification level or efficiency. Resonance energy
      transfer dyes are used for the control of annealing as will be described
      after the following example.
       . . . primers is 3'-labeled with Cy5, no extension can occur.
